Claim

cosmetic or pharmaceutical composition containing such microspheres filled with active product(s) in a suitable carrier can be employed for bringing medications to a determined point of the body, in particular for application to the skin. However, topical application does not generally give the desired effectiveness because the epidermis forms a barrier.

According to the present invention, it has been found that, if the microspheres of the cosmetic or pharmaceutical composition are chosen from a particular size range, the effectiveness of the active product which they contain is greatly increased in a very unexpected manner. Studies conducted by the Applicant Company have made it possible to establish that a considerable improvement was linked with the entry of the microspheres into sebaceous follicles.

aim 1. Pharmaceutical or cosmetic composition for topical application containing, in a suitable carrier, microspheres of polymers or of fatty substances with a melting point higher than 50°C filled with at least one active product, characterised in that at least 80 % by weight of the microspheres have a diameter of between 3 µm and 10 µm.

2. Composition according to Claim 1, characterised in that the polymer is chosen from the group consisting of styrene-based polymers, -alanine-based polymers, polymers derived from acrylic or methacrylic acid, polyesters derived from lactic and/or glycolic acid, crosslinked proteins and proteins coagulated by heat.

5. Composition according to Claim 1, characterised in that the fatty substance is chosen from the group consisting of fatty alcohols and derivatives of alcohols and of fatty acids.

Complete Specification for the invention entitled:

COSMETIC OR PHARMACEUTICAL COMPOSITION CONTAINING MICROSPHERES OF POLYMERS
OR OF FATTY SUBSTANCES FILLED WITH AT LEAST ONE ACTIVE PRODUCT

The following statement is a full description of this invention, including the best method of performing it known to the applicant.

1
COSMETIC OR PHARMACEUTICAL COMPOSITION CONTAINING
MICROSPHERES OF POLYMERS OR OF FATTY SUBSTANCES FILLED
WITH AT LEAST ONE ACTIVE PRODUCT.

5 The present invention relates to a cosmetic or
pharmaceutical composition containing microspheres of
polymers or of fatty substances filled with at least
one active product in a suitable carrier.

10 It is known in the state of the art to prepare
microcapsules in which the active principle is enclosed
and is not in contact with the external environment
(see particularly French Patent 2,218,036 and European
Patent 316,054). However, at the time of application,
the microcapsule can break prematurely and release the
active principle immediately.

15 It is also known to prepare natural or synthetic
polymers in the form of microspheres by crosslinking
these polymers in suspension. A process for the
manufacture of poly- β -alanine microspheres is
described, for example, in French Patent 3,530,450. It
is also known to prepare microspheres of fatty
substances.

20 It is also known that these microspheres are
capable of filling with chemical products, in
particular with active products (see particularly the
above-mentioned French Patent and US Patent 4,690,923).
25 In the present application, an active product means any
product having an activity from the cosmetic or
pharmaceutical viewpoint. The solid product forming the

microsphere can, in fact, serve as an absorbent or adsorbent substrate or also as a binder for many chemical products (see European Patent 211,233). The microspheres filled with active products are employed in a suitable carrier in which the solid substance forming the microspheres is very poorly or not at all soluble. This carrier can be an aqueous solution or an oily phase.

A cosmetic or pharmaceutical composition containing such microspheres filled with active product(s) in a suitable carrier can be employed for bringing medications to a determined point of the body, in particular for application to the skin. However, topical application does not generally have the desired effectiveness because the epidermis forms a barrier.

According to the present invention, it has been found that, if the microspheres of the cosmetic or pharmaceutical composition are chosen from a particular size range, the effectiveness of the active product which they contain is greatly increased in a very unexpected manner. Studies conducted by the Applicant Company have made it possible to establish that this considerable improvement was linked with the entry of the microspheres into sebaceous follicles.

The subject of the present invention is therefore a cosmetic or pharmaceutical composition for topical application containing, in a suitable carrier, microspheres of natural or synthetic polymers or of

Fatty substances with a melting point higher than 30°C, filled with at least one active product, characterized in that at least 40 % by weight of the microspheres employed have a diameter of between 3 µm and 10 µm.

In fact, microspheres which have a diameter in the range defined above enter the sebaceous follicle, but little into the skin. The said microspheres, therefore, selectively and progressively reach the follicular canal, where the active product which they carry diffuses into the follicular canal and the surrounding tissues. On the other hand, the substrate forming the microsphere is subsequently rejected by virtue of the flow of sebum and/or of the growth of hair. Any undesirable reaction of the organism towards the solid compound forming the microspheres is thus avoided.

It should be noted that, when the microspheres have a diameter smaller than 3 µm, they also enter the follicular canals, but the horny layer as well, is a high concentration. Now, this release of the active principle in the horny layer, for example in the case of antiacne preparations, is reflected by the appearance of secondary effects which are undesirable insofar as the active product is released in the regions of healthy skin which are touched by the application and which surround the follicular channels; whereas, in the case of medications acting systemically, the active product is released in a nonvascularized region where, moreover, the horny

3
10
barrier intervenes. Overall, therefore, in both cases, the release of the active principle in the horny layer corresponds to a reduction in the effectiveness of the composition. When the microspheres have a diameter greater than approximately 10 μ m, they remain mostly localized on the surface of the skin without entering it, resulting in an ineffectiveness of the topical application, since the active product can only be released on the horny layer. In both cases, the targeting of the active products is markedly inferior to that which is obtained by making use of the invention.

13
15
In other words, the invention proposes to select the size of the microspheres so as to promote their selective entry into the sebaceous follicles; in the case of acne, the active product is thus brought specifically to the target regions without undesirable secondary effects on the healthy skin regions surrounding the follicular channels; in the case where the active product is a medication which acts systemically, the follicular channel constitutes a highly efficient route of general administration insofar as the diffusion of the active product into this compartment emerges onto a highly vascularized region.

It was not obvious that microspheres capable of entering the hair follicle had to have the dimensions defined above. In fact, the mean diameter of the

pilosebaceous orifices is included in a size range which is quite different from that indicated above in the case of the microspheres; for example, on the forehead, this average diameter is between 52 μm and 92 μm . In man, the surface area of the pilosebaceous orifices situated on the forehead is approximately 0.002 mm^2 (W.J. Cunliffe, W.D.H. Perera, P. Thackray, M. Williams, R.A. Forster and S.M. Williams, British Journal of Dermatology, 1976, 95, 133). Assuming that the contour of the follicular channel is approximately circular, the average diameter of the pilosebaceous orifices can be estimated, according to this paper, at 50.5 μm . This diameter, redetermined by the Applicant Company by measurement of the size of the pilosebaceous orifices situated on the skin of the forehead of six healthy volunteers, is found to be between 52 μm and 92 μm (see study described in test 3 of the present application). This considerable difference between the range of the diameters of pilosebaceous orifices and the range of diameters of the effective microspheres made the invention particularly surprising for the specialist. This surprising nature is furthermore confirmed by the fact that in the abovementioned US Patent 4,690,825, the size indications supplied are aimed only at microspheres which have diameters of between 10 and 100 μm .

The microspheres which have the desired size can be selected by screening, especially in a moist medium,

microspheres obtained by a process giving microspheres which have a more extended range of sizes. It is also possible to obtain microspheres whose sizes are contained in the desired range by suitably directing the process for the manufacture of the microspheres. The size of the microspheres can, for example, be adjusted by choosing the polymerization solvent and the crosslinking agent, or by modifying the rate and the time of stirring of the reaction medium. These various modifications form part of the state of the art and/or are within the competence of the specialist.

The natural or synthetic polymers which can be employed for the manufacture of the microspheres of the composition of the present invention are chosen from those capable of being applied to the skin without undesirable effect and capable of forming microspheres which have the desired dimensions. They must also be compatible with the active product employed.

The polymers which can be employed in the compositions of the present invention may be advantageously chosen from:

- styrene-based polymers, such as polystyrene;
- β -alanine-based polymers, such as poly- β -alanine;
- polymers derived from acrylic or methacrylic acid;
- polyesters derived from lactic and/or glycolic acid;

- proteins crosslinked;

either by glutaraldehyde or by an acid dichloride such as terephthaloyl chloride, or in the presence of an activator such as a carbodiimide;

- proteins coagulated by heat (albumin).

The polymers which can be employed are preferably chosen from polymers based on poly- β -alanine and polyesters derived from lactic or glycolic acid.

The fatty substances which can be employed may be chosen from:

- derivatives of alcohols and of fatty acids, such as tristearin, semisynthetic triglycerides or glycerol monostearate;

- fatty alcohols such as cetyl alcohol.

The fatty substances which can be employed are preferably chosen from fatty substances which have a melting point of approximately between 50°C and 100°C.

The active products which can be employed in the composition according to the invention are those liable to be applied to the skin. They may be chosen from:

- agents for treating acne, such as compounds with action of retinoid type (vitamin A, retinoic acid or its derivatives);

- benzoyl peroxide;

- growth factors of peptidic nature, such as the proteinic or epidermic growth factor (EGF);

- skin-reinforcing agents, such as benzyl

nicotinate;

- agents for treating hair, in particular antiloss or hair regrowth agents, such as minoxidil and antiseborrheoics such as 8-carboxymethylcysteine or octopirox;

- antifungals such as nystatin or econazole;

- astringents, such as aluminium chloride;

- antibiotics, such as erythromycin and tetracycline;

- antivirals, such as vidarabine;

- antihypertensives, such as clonidine hydrochloride;

- antiaanginals, such as nitroglycerine;

- vasodilators, such as bradykinin;

- agents for treating cardiovascular disorders, such as peptides of the tachykinins group, for example "substance P";

- antiinflammatory agents, such as aspirin or hydrocortisone and its derivatives;

- antiallergens such as chromoglycates;

- antipruritics, such as phenothiazine derivatives;

- neurostimulants, such as caffeine or theophylline;

- antidepressant agents, such as lithium salts and, more particularly, lithium carbonate;

- natural compounds employed in neurobiological research, such as capsaicine;

- anaesthetics, such as lidocaine and procaine;
- hormone steroids such as 17- α -oestradiol and 17- β -oestradiol.

The suitable carrier is in aqueous form or in the form of oil.

The carrier in aqueous form may be an aqueous gel obtained with the aid of a gelling agent, such as the crosslinked polyacrylic acid sold under the trade name 'Carbopol' by Goodrich BF or the cellulose derivatives sold under the trade name 'Klucel' by Hercules; or a hydroalcoholic gel containing, for example, propylene glycol. It is also possible to use a lipophilic aqueous solution such as an aqueous solution of silicones.

The oils which can be employed as carriers are liquid or semisolid oils such as triglycerides of C_8 - C_{12} fatty acids and their mixtures, vaseline, liquid paraffin and lanolin.

The pH of the carrier is preferably adjusted to a basic value.

The carrier is in the form of liquid, of gel, of cream, of paste, of pomade or of dry powder. To obtain a paste, a pomade or an ointment, an excipient is added, such as polyethylene glycol, a wax such as beeswax or lanolin.

The cosmetic or pharmaceutical compositions according to the present invention generally contain from 1 % to 40 % by weight of microspheres, at least 80 % of which have diameters of between 3 and 10 μ m.

They also contain from 0.05 % to 50 % by weight of active product.

The microspheres are manufactured by any known process. The polystyrene microspheres are widely marketed. Those of poly- β -alanine can, for example, be prepared according to the processes described in French Patent 3,330,350.

To introduce the active product into the microsphere, the active product is dissolved in a solvent or a mixture of solvents which have a sufficient affinity for the compound forming the microspheres. Among the suitable solvents, especially for poly- β -alanine spheres, there may be mentioned, for example, water, glycerol, ethanol, diethylene glycol, acetone and, in general, water-miscible organic solvents.

When a solvent has been employed to obtain the microspheres filled with active product, the said microspheres may be employed as such or after removal of the solvent remaining therein. This solvent may have remained therein as solvent of the active product and/or as a swelling agent for the microsphere itself when the polymer of which it is made is liable to swell in the said solvent. When the microspheres are employed after removal of the solvent, the active product remains nevertheless trapped in (or on) the microsphere on drying. Swelling of the polymer by a solvent produces microspheres in gel form, provided that the

quantity of solvent does not exceed certain limits, which are different depending on the polymer of which the microspheres are made. The microspheres filled with at least one active product, be they dried or not, are mixed with the chosen carrier.

The cosmetic or pharmaceutical composition obtained is applied in the usual way to the skin, preferably with a gentle massage. In an alternative form, the microspheres are filled with an active product in ionised form: in this case, after application of the composition to the skin, the release of the active product may be accelerated by ionophoresis.

The examples given below, purely by way of illustration, no limitation being implied, will allow the invention to be better understood. Tests A, B and C are measurements provided to explain the remarkable effectiveness of the compounds according to the invention.

Test A:

In this test, the size of the pilosebaceous orifices in man is evaluated. This study was carried out on six healthy volunteers (three men and three women) aged from 25 to 35 years, and it was carried out on the skin of the forehead.

After having carefully cleaned with soap a region of skin of approximately 2 cm², a dye (dark brown direct dye "L'Oreal renovative", marketed by the company known

as '1'Oreal') is chosen and is applied, for fifteen minutes, to the left or right side part of each subject's forehead. At the end of the exposure time, the coloured region is cleaned with a little water to remove the excess dye. This region is photographed with a macrophotographic assembly produced with the aid of an Olympus camera. This apparatus makes it possible to take standardized photographs of the region to be analysed (same distance and same magnification for all the subjects). The dye employed is no longer visible 24 hours after the application.

The distribution of sizes of the pilosebaceous orifices is established by image analysis with the aid of the 'Quantimet 520' apparatus from Cambridge Instruments, from transparencies of the forehead. The apparatus measures the surface area S of the follicle openings and calculates the diameter D of each follicle according to the formula:

$$D = 2 (S/\pi)$$

The results are given in Table 1 below.

The average diameter of the follicles is found to be between 52 μm and 82 μm for all the subjects studied.

Test B:

Tests were carried out to establish the relationship between the size of the microspheres and their entry through the horny layer and the follicles of the human skin.

These tests employed fluorescent polystyrene microspheres of various calibres between 1 μ m and 24 μ m which had the characteristics given in Table II below. These batches of polystyrene microspheres were suspended at a concentration of 10 % by weight in a mixture of triglycerides of C₈-C₁₈ fatty acids marketed under the trade mark "Myglitol 812" by Dynamit Nobel; the tests were performed on the face lift skin of the face of female patients aged from 44 to 66 years.

TABLE II

SUBJECT NO.	SEX	SURFACE FOLICLES	DIAMETER (μ m)		
			Average +/- standard deviation	<90 %	<95 %
1	M	105	82 +/- 34	<128	<150
2	F	102	68 +/- 42	<120	<141
3	F	111	82 +/- 43	<133	<158

The applications are carried out, approximately 4 hours after surgical excision, on facial skin which was not been deep-frozen (storage at 4°C in a cold chamber). The skin is freed from its subcutaneous tissue with a scalpel, and is then slightly stretched and pinned onto a support covered with aluminium. The cutaneous surface is carefully cleaned by wiping with a paper handkerchief, followed by a slight "stripping" carried out with the adhesive tape sold under the trade name "Transpore". The various suspensions of microbeads are then applied with a glass spatula for 15 minutes, with 5 minutes' massage, inside 2.5-cm² application sites delimited by plastic rings bonded using a cyanoacrylate polymer-based adhesive marketed under the name of "Cyanolit". At the end of the application time, the excess product which has not entered the skin is removed with a cotton-stick followed by three very slight applications, to the surface of the skin, of a piece of adhesive tape of trade name "Transpore" (adhering little to the skin and causing no delamination of the horny layer). Biopsies of the application sites, as well as of a control skin region without application, are taken with a "Punch Biopsy" punch 6 mm in diameter and are frozen in liquid nitrogen. The entry of the microbeads into the horny layer and the follicles is then demonstrated, using a fluorescence optical microscope (photomicroscope ILM3, Zeiss, West Germany) on deep-frozen vertical skin

sections 10 μ m to 15 μ m in thickness, produced with the aid of a cryomicrotome (Cryostat Bright, Bright Instrument Company Limited).

The results obtained are the following:

- microspheres 24 μ m in diameter remain localised on the surface of the skin without entering it;
- microspheres 9 μ m to 10 μ m in diameter have a tendency to collect around the follicular canals;
- 7- μ m microspheres have been able to be selectively placed inside the sebaceous follicles;
- microspheres from 1 μ m to 3 μ m have a tendency to enter both the horny layer and the follicles.

Test C:

Tests were carried out to establish the relationship between the size of the microspheres and their entry into the horny layer and the follicles in the rat.

These tests employed poly- β -alanine microspheres; three samples which had average diameters of approximately 2 μ m, 5 μ m and 12 μ m respectively were tested.

The microspheres employed are prepared by crosslinking poly- β -alanine with the aid of glutaraldehyde. This synthesis is described in French Patent 2,530,250. These microspheres are then made fluorescent by an intermediate reaction of hexamethylenediamine with the residual aldehyde functional groups present at their surface, followed by

a reaction with dansyl chloride. The microspheres obtained exhibit a very homogeneous powerful green fluorescence in ultraviolet light. These microspheres have the following characteristics:

- sample 1: diameter = $1.79 \pm 0.96 \mu\text{m}$ (90 % below $2.9 \mu\text{m}$);
- sample 2: diameter = $4.8 \pm 1.1 \mu\text{m}$ (90 % below $6.1 \mu\text{m}$); prepared according to Example 1;
- sample 3: diameter = $12.4 \pm 2.2 \mu\text{m}$ (90 % below $15.1 \mu\text{m}$).

These size measurements were determined by the fluorescence image analysis technique using a "Quantimet 520" apparatus marketed by Cambridge Instruments Co.

The application protocol employed is the following: after anaesthesia with pentobarbital (30 mg/kg dose), 5-cm² application sites are delimited by a plastic ring bonded adhesively to the back of the ICR female nude rat (170-180 g average weight). The various suspensions are applied for 2 hours, in a quantity of 5 to 10 mg/cm², inside these sites. In order to test the influence of massage on the entry of the poly- β -alanine microspheres into the sebaceous follicles, the application is carried out by comparing two massage periods: one minute and five minutes. The animal is bound throughout the experimental period in order to avoid any contact with the region of application. At the end of 2 hours, the excess product which has not entered the skin is carefully removed

with a cotton-stick; three very slight applications of a piece of adhesive tape of trade name "Transpore" (adhering little to the skin and causing no delamination of the horny layer) to the skin surface are then carried out. Biopsies of the application regions are taken (6 mm in diameter) and frozen in liquid nitrogen. The entry of the microspheres into the horny and follicular compartments is then established using the fluorescence optical microscope on deep-frozen vertical skin sections from 10 μ m to 15 μ m in thickness, produced using the cryomicrotome.

In order to test the influence of the carrier on the entry of the poly- β -alanine microspheres, the latter are formulated, at a concentration of 10 % by weight, in the following carriers:

1) Aqueous gel which has the following formulation:

Crosslinked polyacrylic acid sold under the trade name "Carbopol 940" by Goodrich AF	0.4 g
Sodium hydroxide (aqueous solution at a concentration of 10 % by weight)	2.0 g
Water	q.s. 100.0 g

2) Water-silicone carrier consisting of:

Water	5.0 g
Silicone oil sold by Dow Corning under the reference "Q2-3223c"	q.s. 100.0 g

The results are as follows:

a) In suspension in the aqueous gel, microspheres

2 μ m in diameter enter the various layers of the horny layer as well as inside the follicular canals. 8- μ m microspheres are rarely present in the horny layer, after one minute's massage, and are located rather at the entry of the follicular canals; this tendency to enter the follicles is slightly more pronounced after 5 minutes' massage. Microspheres 12 μ m in diameter enter neither the horny layer nor the follicular canals.

b) the water-silicone carrier has an influence on the entry of the 2- μ m microspheres: the latter are more numerous inside the sebaceous follicles and exhibit a uniform distribution in the horny layer. On the other hand, with this carrier, practically no 8- μ m microspheres are found in the horny layer: they are located very deep in the follicles in the vicinity of the sebaceous glands; in this case, massage also has a beneficial influence on the entry of the microspheres into the follicular compartment. As in the case of the aqueous gel, microspheres 12 μ m in diameter enter neither the horny layer nor the follicles.

Examples 1 to 5 below describe processes for the manufacture of poly- β -alanine microspheres, the present or filled with active products and having the desired diameter.

Example 1Preparation of fluorescent poly- β -alanine microspheres

Stage 1 : Preparation of poly- β -alanine spheres in suspension.

5 1125 g of toluene, 444 g of tert-butanol and
0.75 g of copolymer (octadecene/maleic anhydride) (sold
under the trade name "PA-18" by Gulf) are introduced
into a 3-liter reactor equipped with an anchor-type
10 stirrer with a diameter of 90 mm, a nitrogen inlet, a
dropping funnel and a distillation column head. After
heating this mixture to 70°C, 150 g of acrylamide are
added. The temperature is then raised to 100°C and
90 ml of the azeotrope mixture (water/toluene/tert-
butanol) are distilled off. After the end of
15 distillation, the reaction mixture is cooled to 80°C
and the stirring rate is adjusted to 600 rev/min. A
solution of 3.30 g of potassium tert-butyrate in 52 g
of tert-butanol is then added over 10 minutes. The
dropping funnel is rinsed with 75 g of toluene. After
20 stirring for 5 hours at 80°C, the material is allowed
to return to ambient temperature. 11.25 ml of
concentrated hydrochloric acid are then added dropwise
to the mixture.

Stage 2 : Crosslinking of the poly- β -alanine spheres.

25 42 g of an aqueous solution containing 25 % of
formaldehyde are added to the suspension of poly- β -
alanine microspheres thus obtained, over 30 minutes,
with stirring at 600 rev/min and at a temperature of

30°C. After stirring has been continued for 4 hours at this temperature, the suspension is allowed to return to ambient temperature.

After settling, the supernatant solvents are removed and the microspheres are washed twice with 300-ml portions of ethanol. Draining after each washing is carried out by centrifuging at 3,500 rev/min. A washing with 15 litres of water is then carried out continuously and the water is then removed to a final mixture volume of 600 ml is reached.

The crosslinked poly- β -alanine is then dried by freeze-drying and 135 g of a white powder are obtained, in which the diameter of the microspheres is on average $4.80 \pm 1.1 \mu\text{m}$, determined by the image analysis technique using a 'Quantimet 520' apparatus marketed by Cambridge Instruments Co..

Stage C : Reaction with 1,6-diaminohexane

30 g of 1,6-diaminohexane are added to a suspension of 20 g of the poly- β -alanine spheres obtained in stage B in 100 g of water. Stirring is continued for 24 hours at ambient temperature and the material is then drained on a no. 4 glass sinter; lastly, it is washed with water until the aqueous washers are at a neutral pH.

Stage D : Fixing of the fluorescent product.

The microspheres obtained in stage C are suspended in 80 ml of pH 8.9 buffer solution (270 ml of 0.1 M NaHCO_3 solution brought to pH = 8.9 by adding

approximately 30 ml of 0.1 M solution of Na_2CO_3). 3 g of dansyl chloride in solution in 80 g of acetone are introduced into this suspension. The mixture is heated for 10 minutes at solvent reflux and is then drained on a no. 4 glass sinter and finally washed with acetone until all traces of dansyl chloride have disappeared from the solvent wash, monitored by UV detection at 250 nm. The spheres are first dried in air and then under reduced pressure at ambient temperature. The final colour of the microspheres is light yellow.

Example 1

Preparation of poly-L-alanine microspheres filled with dansyl benzoxide

Stage A : Preparation of poly- β -alanine spheres in suspension.

This stage is identical with stage A of Example 1.

Stage B : Crosslinking of the poly- β -alanine microspheres

10 g of aqueous solution containing 25 % by weight of glutaraldehyde are added steadily over 15 minutes to a suspension of poly- β -alanine microspheres obtained in stage A, kept vigorously stirred (600 rev/min) and at a temperature of 50°C. After stirring has been continued for 4 hours at this temperature, the suspension is allowed to return to ambient temperature. After settling, the supernatant solvents are removed and the microspheres are washed twice with 300-ml portions of ethanol. The draining after each washing is carried out

by centrifuging (3,500 rev/min). Washing with 13 litres of water is then carried out continuously and the water is then removed until a final mixture volume of 600 ml is reached. The swollen polymer is finally dried by freeze-drying and 132 g of white powder are obtained, in which the diameter of the microspheres is on average $4.05 \pm 2.02 \mu\text{m}$, measured according to the same method as in Stage B of Example 1.

Stage C : Reduction of the residual aldehyde functional groups.

2.2 litres of water are added to 150 g of crosslinked poly- β -alanine microspheres obtained in stage B and are homogenized by stirring. After cooling to a temperature of between 5 and 10°C, a cooled solution of sodium borohydride in water (5.2 g of NaBH₄ in 600 ml of water cooled to 5°C) is added slowly. The reaction mixture is kept between 5 and 10°C for 5 hours and the pH is then brought to 7 by adding acetic acid.

After centrifuging the mixture and dispersing the solid residue in 450 ml of water, it is subjected to continuous washing with 5 litres of water (washing in an "Amicon" cell equipped with a 0.2- μm Diapor filter, pressure 2 bars, stirring throughout the washing). The hydrated microspheres are then dried by freeze-drying. The absence of colour in the presence of Schiff's reagent makes it possible to conclude that the residual aldehyde functional groups have been reduced. After analysis, the diameter of the microspheres is identical

with that of the original microspheres.

Stage D : Introduction of the active product.

44.3 g of benzoyl peroxide (75 % by weight grade) are dissolved in a mixture made up of 1123 g of acetone and of 373 g of water; 30 g of the microspheres prepared in stage C are then suspended in this solution. The suspension is concentrated in a rotary evaporator at reduced pressure, at a temperature not exceeding 35°C, to a total weight of 262 g of suspension.

The benzoyl peroxide content of the suspension obtained is 9.1 % by weight.

Example 3

Preparation of poly-L-alanine microspheres filled with benzyl nicotinate.

Stages A to C : Preparation of the microspheres.

Stages A to C are carried out as in Example 2.

Stage D : Introduction of the active product.

2 g of benzyl nicotinate are dissolved in a mixture made up of 40 g of water and 40 g of ethanol; 10 g of microspheres prepared in Stage C are then suspended in this solution. The suspension is kept stirred for 2 hours and the ethanol is then removed in a rotary evaporator, the temperature being maintained at a value below 35°C. Finally, the microspheres are dried by freeze-drying.

Example 4

Preparation of poly-L-alanine microspheres filled with

Benzyl nicotinate.

Stages A to C are carried out as in Example 1 and stage D for introducing benzyl nicotinate as active product, as in Example 3.

Example 3Preparation of poly- α -olefin microspheres filled with retinoic acid

Stages A to C : Preparation of the microspheres.

Stages A to C are carried out as in Example 1.

Stage D : Introduction of the active product.

15 mg of butylhydroxytoluene (antioxidant) are dissolved in 30 g of 1,2-propylene glycol at a temperature of 30°C. 24 mg of retinoic acid are dissolved in 10 g of the mixture obtained above, at ambient temperature, under argon and in the absence of light. The solution obtained is filtered with the aid of 0.1 μ m "Millipore" filters. 3 g of the microspheres prepared in stage C are suspended in this solution in the absence of light and under a stream of argon.

Mixing is carried out with a spatula. After two hours' absorption, a yellow powder is obtained. Determination of retinoic acid in the spectrophotometer ($\lambda = 358.8$ nm) after desorption of the active principle into dimethyl sulphoxide.

Theoretical concentration : 0.16 %.

Calculated concentration : 0.157 %.

The gel is frozen with stirring and then freeze-dried.

calculated concentration: 11.5 % (by wt

determination at 230 nm after suspending in ethanol).

Example 2:

- 3 Preparation of fatty substance microspheres filled with retinoic acid.

Stage 1 : Preparation of the solution of active principle.

- 10 200 mg of all-trans retinoic acid are dissolved in 5 ml of 1,2-dichloroethane, in the absence of light.

Stage 2 : Coating of the active principle with fatty substance microspheres.

- 15 4.75 g of tristearin and 250 mg of glycerol monostearate are introduced into a stainless steel reactor provided with a nitrogen inlet and equipped with a magnetic stirrer and a heating plate. Mixing is carried out by stirring at a temperature of 80°C. The solution of active principle prepared in stage 1 is then added in the absence of light. The mixture
- 20 obtained is kept stirred at 80°C and is then blown, under a nitrogen pressure of 7 bars, into a spraying nozzle connected to the reactor apparatus (1/4 JCC-SS-30.B152-SS, Mani). The microspheres consisting of the retinoic acid coating with the mixture of
- 25 tristearin-glycerol monostearate fatty substances are then formed downstream of this spraying nozzle inside a dilution chamber (length: 85 cm) and are then collected on a grid (Millipore, 24 cm in diameter,

preferably, "1 TT30 100 50"). A yellow-coloured powder is obtained. The retinoic acid content of the microspheres obtained is 2.73 % by weight. The diameter of the microspheres, determined by image analysis (HBO-Wideoplan Apparatus, Kontron) is $0.43 \pm 0.10 \mu$.

Example 9 to 13 below relate to the preparation of cosmetic or pharmaceutical compositions from microspheres filled with active product and prepared in Examples 3 to 8.

Example 9

Preparation of poly(lactide-co-glycolide) microspheres filled with 6-[3-(1-adamantyl-4-methoxyphenyl)]-2-naphthoic acid

0.3 g of poly(lactide-co-glycolide) sold by Dupont under the trade name of "Medicorb 6030 EA" and 5 mg of 6-[3-(1-adamantyl-4-methoxyphenyl)]-2-naphthoic acid are dissolved in 15 ml of methylene chloride. The organic solution obtained is emulsified with mechanical stirring (3000 rev/min) in 100 ml of an aqueous gel containing 0.3 g of hydroxypropyl cellulose sold by Aquelon under the trade name of "Klucel 2F". Mechanical stirring is continued for 3 hours, which permits the progressive and complete evaporation of methylene chloride.

The microspheres obtained are recovered, washed three times with distilled water and freeze-dried. The size distribution of the microspheres obtained by this method is analysed with a microscope. The diameter of

Example 1:

Preparation of poly-L-alanine microspheres filled with
alanidine hydrochloride

Stage A and C: Preparation of the microspheres.

Stages A and C are carried out as in Example 2.

Stage B: Introduction of the active product.

37.5 mg of alanidine hydrochloride are dissolved
in 15 g of water in the absence of light, and 3 g of
microspheres prepared in stage C are then added to 12 g
of the above solution. Mixing is carried out with a
spatula. After 2 hours' absorption, a white powder is
obtained. The microspheres are then dried by freeze-
drying. Determination of alanidine hydrochloride in the
finished product is carried out by HPLC analysis after
desorption of the active principle.

Calculated concentration: 1.5.

Example 2:

Preparation of poly-D-alanine microspheres filled with
minoxidil

Stage A and C: Preparation of the microspheres.

Stages A and C are carried out as in Example 2.

Stage B: Introduction of the active product.

2 g of minoxidil are dissolved at 30°C in a
mixture made up of 75 g of ethanol and 75 g of water.
3 g of poly-D-alanine spheres obtained according to
stage C are introduced into this solution. The mixture
is stirred for 1 hour in the rotary evaporator and the
solvent is then evaporated off until a gel is obtained.

the spheres is between 1 and 15 μ m, with an average size of 5 μ m; more than 10 % of the microspheres have a diameter of between 3 and 10 μ m.

The encapsulation is checked in the following manner:

1) Inspection of the microspheres by optical microscopy (fluorescence) shows fluorescent spheres and the absence of free crystals of active principle;

2) inspection by electron microscopy confirms the absence of crystals outside the spheres and the absence of crystals on the surface of the spheres.

To evaluate the degree of encapsulation of the active principle in the microspheres, a sample of the microspheres obtained above (100 mg) is extracted with tetrahydrofuran (5 ml); it is then filtered; the filtrate is analysed by high performance liquid chromatography; the degree of encapsulation of 5-(3-(1-adamantyl-4-methoxyphenyl))-2-naphthoic acid is 0.71 %.

Example 14 :

Preparation of poly(lactide-co-glycolide) microspheres filled with retinoic acid

Microspheres filled with retinoic acid can be obtained by the same method of preparation as in Example 11: the 5 mg of 5-(3-(1-adamantyl-4-methoxyphenyl))-2-naphthoic acid are then replaced by 5 mg of retinoic acid.

Example 11 :

Preparation of trioleate microspheres filled with 2-benzoylphenylacetoxycarboxylic acid

Microspheres are prepared from triglycerides, namely a hydrogenated palm oil marketed under the name of "Mofison 381" by Societe Nobel, by a spraying process with the aid of a pressurized spraying unit.

The triglyceride and the active principle, namely 2-benzoylphenylacetoxycarboxylic acid at a concentration of 11 g by weight relative to the weight of triglyceride, are melted at 60°C under nitrogen atmosphere and in the absence of light in a thermostated steel lens steel reactor. The molten mixture is propelled with nitrogen (6×10^5 kPa pressure) up to the nozzle at a certain flow rate and the spraying is carried out at the nozzle under nitrogen pressure (3×10^5 kPa pressure).

The spraying is carried out in a sealed stainless steel vessel which has a temperature gradient from approximately -150°C at the bottom to 10°C at the top. This gradient is created by previous immersion of liquid nitrogen into the bottom of the vessel.

As a general rule, depending on the type of nozzle which is chosen, the spraying nitrogen pressure and the flow rate of the liquid determine the average diameter of the spheres obtained. Thus, the lower the flow rate, the smaller the droplets leaving the nozzle and, consequently, the microspheres at the bottom of the vessel. Furthermore, the higher the spraying pressure,

the smaller the diameter of the spheres and the more homogeneous the size distribution.

In this example, uniform microspheres are obtained without free crystal: of active principle which are visible under the microscope. the diameter of the spheres varies from 1 to 15 μ , with a mean diameter below 10 μ . the proportion of active principle incorporated, determined by high performance liquid phase chromatography, was established as 15 %.

Example 10

A gel is prepared by mixing the following ingredients:

Microsphere suspension prepared according to Example 2	361 g
Water q.s.	300 g
Crosslinked polyacrylic acid sold under the trade name "Carbopol 940" by Goodrich BP	0.5 g
Sodium hydroxide q.s.	pH = 7

When applied to the skin by massage until it dries completely, twice daily for 30 days, this preparation has excellent antitumor properties.

Example 11

A gel is prepared by mixing the following ingredients:

Microsphere suspension prepared according to Example 2	331 g
Water q.s.	145 g

When applied to the skin by massage until it

enters completely, twice daily for 30 days, this preparation has excellent antilactone properties.

Example 14

A gel is prepared by mixing the following

Ingredients:

Microspheres as herein prepared according to

Example 1 100 g

Crosslinked polyacrylic acid sold under the trade name "Cartopol 940" by Goodrich CF ... 25 g

Water q.s. 1.5 ltr

Sodium hydroxide q.s. pH = 7

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antilactone properties.

Example 15

A gel is prepared by mixing the following

Ingredients:

Microspheres prepared according to

Example 3 (as many...as are necessary) 1 g

Crosslinked polyacrylic acid sold under the trade name "Cartopol 940" by Goodrich CF 0.6 g

Water q.s. 100 g

Sodium hydroxide q.s. pH = 7

When applied by massage until it enters completely, twice daily for 30 days, to certain parts of the body, for example the breasts, this preparation contributes to making them firmer.

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antineoplastic properties.

Example 10

A gel is prepared by mixing the following ingredients:

- Microspheres obtained in Example 1 50 g
- Cellulose derivatives sold under the trade name "Glucol" by Hercules 1.5 g
- Water q.s. 100 g

When applied to the skin by massage until it enters completely, twice daily for 2 to 3 weeks, this preparation has excellent antihypertensive properties.

Example 11

A gel is prepared by mixing the following ingredients:

- Microspheres obtained in Example 7 17.25 g
- Cellulose derivatives sold under the trade name "Glucol" by Hercules 1.55 g
- Water 15.22 g
- Propylene glycol q.s. 100 g

This gel is applied twice daily to a scalp which has undergone a considerable hair loss. After 3 months' treatment at a rate of 1 ml per application a significant improvement is noted.

Example 21

A gel is prepared by mixing the following

Ingredients:

- Microspheres obtained in Example 1 1.5 g
- Cellulose derivatives sold under the trade name
"Mucosat" by Hercules 1.5 g
- Water q.s. 100 g

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antitumor properties.

Example 22

A gel is prepared by mixing the following

Ingredients:

- Microspheres prepared according to

Example 8 1.5 g

- Crosslinked polyacrylic acid sold under the name
"Carbopol 940" by Goodrich AF 0.5 g
- Water q.s. 100 g
- Sodium hydroxide q.s. pH = 7

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antitumor properties.

Example 23

A gel is prepared by mixing the following

Ingredients:

- Microspheres prepared according to

Example 10 1 g

- Crosslinked polyacrylic acid sold under the name

"Carbopol 940" by Goodrich 27		0.4 g
- Water	q.s.	100 g
- Sodium hydroxide	q.s.	pH = 7

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antiseptic properties.

Example 11

A gel is prepared by mixing the following ingredients:

- Microspheres prepared according to		
Example 11		20 g
- Crosslinked polyacrylic acid sold under the name		
"Carbopol 940" by Goodrich 27		0.4 g
- Water	q.s.	100 g
- Sodium hydroxide	q.s.	pH = 7

When applied to the skin by massage until it enters completely, twice daily for 30 days, this preparation has excellent antiinflammatory properties.

the group consisting of agents for treating acne, antineoplastic agents, agents for treating hair conditions, astringents, antibiotics, anti-asthmatics, antihypertensives, anticonvulsant vasodilators, agents for treating cardiovascular disorders, antiinflammatory agents, antidiarrheals, antidiuretics, growth factors of peptidic or proteinic nature, neurostimulants, antidepressant agents, chemical compounds developed in neurobiological research, immunostimulators and hormone steroids.

8. Composition according to Claim 7, characterized in that it contains vitamin A, retinoic acid or one of its derivatives, or benzoyl peroxide, as agent for treating acne.

9. Composition according to Claim 7, characterized in that it contains minoxidil as antiloss or hair regrowth agent and 5-carboxymethyllysine or osteoponin as antihemorrhagic agent.

10. Composition according to Claim 7, characterized in that it contains cystatin or eschercol as antifungal.

11. Composition according to Claim 7, characterized in that it contains aluminium chloride as astringent.

12. Composition according to Claim 7, characterized in that it contains erythromycin or tetracycline as antibiotic.

13. Composition according to Claim 7, characterized in that it contains vidarabine as antiviral agent.

14. Composition according to Claim 7, characterized in

that it contains alonidiaz hydrochloride as antihypertensive.

15. Composition according to Claim 7, characterized in that it contains nifedipine as vasodilator.

16. Composition according to Claim 7, characterized in that it contains a system of the benzothiazine group, in particular "substance B", as agent not affecting cardiovascular disorders.

17. Composition according to Claim 7, characterized in that it contains aspirin or hydrocortisone or its derivatives as antiinflammatory agent.

18. Composition according to Claim 7, characterized in that it contains a chromoglycate as antiallergen.

19. Composition according to Claim 7, characterized in that it contains a phenothiazine derivative as antiemetic.

20. Composition according to Claim 7, characterized in that it contains the epididymis growth factor (EGF) or growth factor of peptidic nature.

21. Composition according to Claim 7, characterized in that it contains caffeine or theophylline as neurostimulant.

22. Composition according to Claim 7, characterized in that it contains a lithium salt as antidepressant.

23. Composition according to Claim 7, characterized in that it contains capsaicin as natural compound employed in neurobiological research.

24. Composition according to Claim 7, characterized in
